

This application is a continuation of application Ser. No. 07/485.659 filed Feb. 27, 1990 now abandoned.

## BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a crankshaft assembly 10 including a flywheel, for an internal combustion engine. More specifically, the present invention relates to a trank shaft assembly for an internal combustion engine, which can effectively shift a resonance frequency of a flexural or bending vibration of the crankshaft assembly out of a target frequency band of a forced vibration which results such as frequency band of a forced vibration which results such as during acceleration of a vehicle so as to effectively prevent occurrence of a thick sound or noise in an engine room. while ensuring a quick response for clutch engaging and disengaging operations, and/or which can prevent occur- 20 rence of a fore and aft vibration of a vehicle floor at the time of engagement of the clutch.

2. Description of the Background Art

In a known crankshaft assembly for an internal combustion engine, a flywheel is directly connected to a crankshaft 25 to use a mass of the flywheel mainly for reducing a torsional vibration generated in a rotating direction of the crankshaft assembly due to periodic torque fluctuation. However, the mass of the flywheel tends to generate a flexural or bending vibration in an axial direction of the crankshaft which causes 30 a thick sound or noise in an engine room and thus in a vehicle compartment for an automotive vehicle, particularly at the time of the acceleration of the vehicle.

Accordingly, there has been proposed a trankshaft assembly such as disclosed in Second Japanese Patent Publication 35 No. 57-58542, wherein the flywheel is connected to the crankshaft through an elastic or flexible plate. The elastic plate has a rigidity in its rotating direction large enough for effectively transmitting the power between the crankshaft and a transmission through a clutch, while the elastic plate 40 has a rigidity in the axial direction small enough for shifting a resonance frequency of the bending vibration out of a frequency band of a forced vibration which results during the most frequently used engine speed (4,000 rpm) so as to overcome the above-noted problem.

However, the background art as mentioned above has the following problems.

When the rigidity of the elastic plate in the axial direction (hereinafter referred to as "the axial rigidity") is too small, 50 a clutch stroke for engaging and disengaging the clutch is likely to become larger, resulting in a delayed response of the clutch engaging and disengaging operations leading particularly to failure of the clutch disengagement which is likely to cause such as an engine stall. On the other hand, 55 when the axial rigidity of the elastic plate is too large, the deviation of the resonance frequency of the bending vibration from the target frequency band of the forced vibration can not be ensured.

Further, in the background art, when the flywheel is 60 rotated, an axial run-out occurs on an engaging surface of the flywheel with a clutch facing of a clutch disc provided adjacent to the flywheel, due to a processing error and an assembling error of the elastic plate and the flywheel. Accordingly, when the clutch is engaged, a vibration is 65 generated by a combination of the run-out of the engaging surface of the flywheel and the torque fluctuation of the

flywheel

Ingine, which is amplified by a vibration general the combustion in the engine cylinders and corresponding movements of associated members so as to cause a fore and aft vibration of the vehicle floor. Such vibration is uncomfortable for the driver and passengers in the vehicle compartment.

#### SUMMARY OF THE INVENTION

+ lywheel ~

Therefore, it is an object of the present invention to provide a crankshaft assembly for an internal combustion engine that can eliminate the above-noted defects inherent in the background art.

Tywheel.

It is another object of the present invention to provide a can effectively shift a resonance frequency of a flexural or bending vibration of the crankshaft assembly out of a target frequency band of a forced vibration, particularly out of a target frequency band which results during acceleration of a vehicle so as to effectively prevent occurrence of a thick sound or noise in an engine room, while ensuring a quick response of the clutch engagement and disengagement operations so as to prevent particularly the failure of the clutch disengagement which is likely to cause such as an engine stall.

flywheel

flywheel -

It is still another object of the present invention to provide a crankshaft assembly for an internal combustion engine that can prevent occurrence of a fore and aft vibration of a vehicle floor at the time of the engagement of the clutch by effectively eliminating an axial run-out of an engaging surface of a flywheel with a clutch facing generated during rotation of the flywheel.

To accomplish the above mentioned and other objects, according to one aspect of the present invention, a crank-shaft assembly for an internal combustion engine comprises a crankshaft for transmitting a driving power to a transmission through a clutch, an elastic member fixed to the crankshaft, and a flywheel fixed to the elastic member such that the flywheel is supported in an elastic relationship with the crankshaft.

The flywheel has an engageable surface at a side opposite to the elastic member in an axial direction of the crankshaft, and the engageable surface is engageable with an associated member of the clutch to receive a load therefrom in the axial direction when the engageable surface is engaged with the associated member of the clutch.

The elastic member has a first predetermined rigidity in its rotating direction, the first predetermined rigidity being large enough to effectively transmit the driving power to the transmission through the clutch. On the other hand, the elastic member has a second predetermined rigidity in the axial direction, the second predetermined rigidity being small enough to shift a resonance frequency of a bending vibration out of a target frequency band of a forced vibration, while ensuring to prevent a failure of disengagement between the engageable surface of the flywheel and the associated member of the clutch.

According to another aspect of the present invention, a method for forming a crankshaft assembly for an internal combustion engine comprises steps of fixing a flywheel to an elastic member to form a unit, assembling the unit onto the crankshaft with the elastic member mounted onto the crankshaft so as to support the flywheel in an elastic relationship with the crankshaft, and processing an engageable surface of the flywheel, which is engageable with an associated member of a clutch, based on an assembled condition between the

flywheel

e Marie de Sala Marie de Carlos

flywheel

flywheel

elastic member and the crankshaft so as to minimum out of the engageable surface.

According to still another aspect of the present invention. a crankshaft assembly for an internal combustion engine comprises a crankshaft for transmitting a driving power to a stransmission through a clutch, an elastic member fixed to the crankshaft, and a flywheel fixed to the elastic member such that the flywheel is supported in an elastic relationship with the crankshaft.

The flywheel has an engageable surface at a side opposite to the elastic member in an axial direction of the crankshaft, and the engageable surface is engageable with an associated member of the clutch to control transmission of the driving power between the crankshaft and the transmission.

The engageable surface is designed to have an axial run-out which is no more than 0.1 mm for ensuring a smooth engagement with the associated member of the clutch.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be understood more fully from the detailed description given hereinbelow and from the accompanying drawings of the preferred embodiment of the invention, which are given by way of example only, and are not intended to be limitative of the present invention.

In the drawings:

FIG. 1 is a longitudinal cross section of a crankshaft assembly for an internal combustion engine according to a first preferred embodiment of the present invention;

FIG. 2 is a graph of vibration level versus frequency showing a shift of a resonance frequency of a flexural or bending vibration by changing a rigidity of an elastic or flexible plate in an axial direction of a crankshaft;

FIG. 3 is a longitudinal cross section of a crankshaft assembly fop an internal combustion engine according to a second preferred embodiment of the present invention; and

FIG. 4 is a graph of fore and aft vibration of vehicle floor versus flywheel run-out amount, showing a relationship 40 between an amount of an axial run-out of a flywheel and a fore and aft vibration of a vehicle floor.

# DESCRIPTION OF THE PREFERED EMBODIMENT

Now, crankshaft astembly for an internal combission engine according to preferred embodiments of the present invention will be described hereinbliow with reference to FIGS. 1 to 4.

FIG. 1 shows a first preferred embodiment of the present invention. An angine crankshift 1 is connected to pistons through respective connecting rods in a known manner for receiving the driving power therefrom. In elastic plate, substantially of a disc shape is fixed to one end of the crankshift 1 by a plurality of bolts 3 the elastic plate 2 is formed at its outer peripheral edge portion with an axially extending section 2a to which a ring gear R is fixed, the ring gran R engages with pinion gears of an engine starter motor for transmitting the driving power from the engine starter motor to the crankshaft 1 when starting the engine.

An annular reinforcing member 4 is disposed between the elastic plate 2 and heads of the bolts 3. The reinforcing member 4 is formed at its outer periphers edge portion with 6 acylindrical section 4 extending in anixial direction of the crankshaft 1 and with a radially extending section 4.

Fig. 5 is an enlarged view of a central part of the flywheel assembly shown in Fig. 3.

### DESCRIPTION OF THE PREFERRED EMBODIMENT

Now, a [crankshaft] <u>flywheel</u> assembly for an internal combustion engine according to preferred embodiments of the present invention will be described hereinbelow with reference to FIGS. 1 to 4.

present invention. [An] A driving shaft in the form of an engine crankshaft 1 is connected to pistons through respective connecting rods in a known manner for receiving the driving power therefrom. An elastic [plate] member 2 of this example is substantially of a disc shape, and is fixed, at its inner portion 2f, to one shaft end of the crankshaft 1 by a plurality of bolts 3. As shown in Fig. 1, the elastic member or plate 2 substantially of a disc shape is in the form of a circular plate. The elastic plate 2 [is formed at its] has an outer peripheral [edge] portion 2b which is formed with an axially extending [section] flange 2a to which a ring gear R is fixed. The ring gear R engages with pinion gears of an engine starter motor for transmitting the driving power from the engine starter motor

to the crankshaft 1 when starting the engine. The inner portion 2f of the elastic plate 2 is surrounded by the outer portion 2b of the elastic plate 2.

An annular reinforcing member 4 is disposed between the elastic plate 2 and heads of the bolts 3. The reinforcing member 4 is formed at its outer peripheral edge portion with a received portion 4a which is in this example cylindrical [section 4a] and [extending] extends in an axial direction of the crankshaft 1. [and with] The reinforcing member 4 of this example further has a radially outwardly extending [section] flange 4b in the form of an outward flange, as shown in Fig. 1. The inner portion 2f of the elastic plate 2 is clamped between the reinforcing member 4 and the shaft end of the crankshaft 1.

A flywheel body 5 of an annular shape is fixed to the elastic plate 2 at their respective outer peripheral [edge] portions 5a and 2b through a plurality of bolts 6 and corresponding reinforcing ring members 7 disposed between the elastic plate 2 and heads of the bolts 6. The annular flywheel body 5 has an inner portion 5h [a stepped inner peripheral edge surface] defining a central mounting [opening] hole 5b for receiving the cylindrical received portion 4a of the reinforcing member 4 therein. The [stepped] inner peripheral [edge] surface of the flywheel

-3(iii) -

body 5 is stepped and has a first surface section 5c extending axially, a second surface section 5d extending radially outward from the first surface section 5c and a third surface section 5e extending axially from the second surface section 5d. Each of the first and third surface sections 5c and 5e faces radially inwardly, and the second surface section 5d faces axially away from the elastic plate The [axial section] axially extending, cylindrical received portion 4a of the reinforcing member 4 is in a slidable contact with the first surface section 5c of the flywheel body 5, and the radial [section] outward flange 4b of the reinforcing member 4 is spaced from the second surface section 5d of the flywheel body 5 by a predetermined [distance] clearance 10 for allowing an axial movement of the flywheel body 5 along with the elastic plate 2. A radially extending [inner] first side surface 5f of the flywheel body 5 facing the elastic plate 2 is spaced apart from the elastic plate 2 by a predetermined [distance] clearance 11 for ensuring an elasticity of the elastic plate 2.

In the example shown in Fig. 1, the side surface 5h of the flywheel body 5 has an outer side surface section 5j and an inner side surface section 5k surrounded by the outer side surface section 5j. The outer side surface section 5j

U.S. Patent No. 5,465,635 Reissue Application Art Unit: 3502

-3(iv) -

faces toward the elastic plate 2 and is fastened to the outer portion 2b of the elastic plate 2. The inner side surface section 5k also faces toward the elastic plate 2. The inner side surface section 5k is raised from the outer side surface section 5j toward the elastic plate 2.

The flywheel body 5 further includes a radially extending side surface 5g at a side axially opposite to the radial surface 5f or the elastic plate 2. The [radial] radially extending side surface 5g is an engaging surface which is engageable with a clutch facing 8 of a clutch disc 9 of a clutch in a known manner so as to control the transmission of the power between the crankshaft 1 and a engh ng Heb Hala transmission.

5

10

en in the state of the state of

plate 2 at Weir respective outer peripher through a flurality of bols 6 an ions Sa and rresponding scinforcing members 7 disposed between the lastic plate 2 and heads of the bolts 6. The annular flywhee body 5 has a stepped inner peripheral edge surface defining a mounting opening 5b for receiving the rainforcing memb n. The stepper inner peripheral edge surface hi ending axially, second section ending radially outward from the first section 5, and fird section Sextending axially from the second Sd. The axial section 40 of the reinforcing member 4 is in slidable contact with the first section Sc of the Bywheel bod 5, and the radial section 4b of the reinforcing member 4 spaced from the second section 3d of the 6 wheel body 5 a predetermined distance for allowing as axial moveme he flywheel llong with the elastic plate 2. A pidiall extending inner surface \$f of the bywheel facing the elastic plate 2 is spaced apart from the elastic plate predefermined distance for ensuring an elasticity of th elastic plate 2.

The flywheel body 5 further includes a radially externant surface 5g at a size axially opposite to the radial surface 5g or the elastic plate 2. The radial surface 5g is engageable with a clusten facing 8 of a clutch disc 9 of clutch in known manner so as to control the transmission of the power harmon, the creakes and a transmission of the power

A rigidity of the elastic plate 2 in its rotating direction (hereinafter referred to as "the circumferential rigidity") is set large enough for effectively transmitting the power between the crankshaft 1 and the transmission through the clutch, while a rigidity of the elastic plate 2 in the axial direction (hereinafter referred to as "the axial rigidity") is set small enough for shifting a resonance frequency of the flexural or bending vibration out of a frequency band of a forced vibration which results during the acceleration of the engine.

As described in the background art, when the axial rigidity of the elastic plate is too small, a clutch stroke for engaging and disengaging the clutch becomes larger, i.e. a clutch stroke loss gets larger, resulting in delayed response of the clutch engaging and disengaging operations leading particularly to the failure of the clutch disengagement which is likely to cause such as an engine stall. On the other hand, when the axial rigidity of the elastic plate is too large, the deviation of the resonance frequency of the bending vibration from the target frequency band of the forced vibration can not be attained.

To overcome the above-noted problem, the axial rigidity of the elastic plate 2 in this embodiment is set to 600 kg/mm to 2200 kg/mm, wherein an axial displacement of the radial surface 5g of the flywheel 5 is no more than 1 mm when an axial load or force 600 kg to 2200 kg is applied to the radial surface 5g. By selecting a value of the axial rigidity of the elastic plate 2 within the foregoing range, not only is the failure of the clutch disengagement effectively prevented, but also the deviation of the resonance frequency of the bending vibration from the frequency band of the forced vibration, during the acceleration of the engine in this embodiment, is effectively attained so as to prevent generation of the thick sound or noise in the engine room.

Specifically, it is confirmed that the failure of the clutch disengagement, i.e. the failure of the disengagement between the radial surface 5g of the flywheel and the clutch facing 8 of the clutch disc 9, happens when an axial displacement of the radial surface 5g at the time of engage-

ment with the clutch facing 8 exceeds 5% of stroke (normally at 7 mm to 8 mm) [ful ing and disengaging the clutch. The normal clutch stroke is a distance between the radial surface 5g of the flywheel body 5 and the clutch facing 8 in a disengagement or released 5 condition of the clutch. Accordingly, considering that an axial load applied to the flywheel body 5 through the clutch facing 8 is normally at 150 kg to 200 kg, the lower limit value 600 kg/mm of the axial rigidity of the elastic plate is selected, wherein the axial displacement of the radial surface 5g is within 5% of the normal clutch stroke when applied with the axial load 150 kg to 200 kg, as shown in TABLE

TABLE 1

AXIAL LOAD	AXIAL RIGIDITY	AXIAL DISPLACEMENT
150 kg	500 kg/mm	0.30 mm
	_	(3.8 to 4.3%)
200 kg	500 kg/mm	0.40 mm
		(5.0 to 5.7%)
150 kg	600 kg/mm	0.25 mm
		(3.1 to 3.6%)
200 kg	600 kg/mm	0.33 <del>cam</del>
		(4.1 to 4.7%)
150 kg	700 ka/mm	0 21 mm
		(2.6 to 3.0%)
200 kg	700 kg/mm	0.29 mm
	-	(3.6 to 4.1%)

(wherein, percentage denotes a rate of the axial displacement relative to the normal clutch stroke which is 7 to 8 mm) 30

As seen from TABLE 1, the lower limit value 600 kg/mm of the axial rigidity of the elastic plate 2 ensures the axial displacement of the radial surface Sg of the flywheel body 5 within 5% of the normal clutch stroke, i.e. the axial displacement of the radial surface 5g is between 0.25 to 0.33 mm or between 3.1 to 4.7% relative to the normal clutch stroke when applied with the normal axial load at 150 to 200 kg through the clutch facing 8, so that the failure of the clutch disengagement is effectively prevented. Naturally, the larger the axial rigidity of the elastic plate gets, the smaller the axial displacement of the flywheel gets.

Now, the axial rigidity of the elastic plate 3 will be considered in view of shifting of the resonance frequency of the bending vibration out of a frequency band of a forced 45 vibration which results during the acceleration of the engine. where the sound or noise generated by the bending vibration is the most significant. It is confirmed that the sound or noise generated by the bending vibration is effectively reduced when the resonance frequency is shifted out of the frequency 50 band of the forced vibration during the acceleration of the engine.

Ny Name and American

FIG. 2 is a graph of bending vibration level versus frequency showing a result of experiments using various elastic plates having different axial rigidities. The frequency 55 band of the forced vibration during the acceleration of the engine is 200 Hz to 500 Hz. In FIG. 2, a line Ao shows a relationship between the frequency and the bending vibration level without using the elastic plate, i.e. the flywheel is directly connected to the crankshaft. As can be seen, a 60 resonance frequency of the line Ao is within 200 Hz to 500 Hz, which causes the sound or noise problem. A line A1 is derived by the elastic plate having the axial rigidity of 2200 kg/mm, a line A2 is derived by the elastic plate having the axial rigidity of 1700 kg/mm, line A3 is derived by the 65 elastic plate having the axial rigidity of 1200 kg/mm, and a line A4 is derived by the elastic plate having the axial

rigidity of 1000 kg/mm. As can be seen, the resonance frequency of each of the lines A1 to A4 is shifted out of the frequency band 200 Hz to 500 Hz, and further, the vibration level of each of the lines A1 to A4 is considerably lower than the line A0 within the frequency band 200 Hz to 500 Hz. Though the line A1 has a vibration level higher than the line A0 around 200 Hz, this happens in a very small range of frequency. Accordingly, the value 2200 kg/mm is selected as an upper limit value of the axial rigidity of the elastic plate, and the value 1700 kg/mm is selected as a more preferable upper limit value of the axial rigidity.

In light of the above, the axial rigidity of the elastic plate 2 in this embodiment is selected at 600 kg/mm to 2200 kg/mm, and preferably at 600 kg/mm to 1700 kg/mm.

As understood from the above description, this first embodiment, when the crankshaft 1 is rotated, the flywheel body 5 is ensured to rotate with the crankshaft 1 by means of the large circumferential rigidity of the elastic plate 2. When the clutch is engaged and the engine is accelerated, the driving power is transmitted to the transmission with a very low bending vibration level by means of the axial rigidity of the elastic plate being no more than 2200 kg/mm, so that the vehicle compartment can be kept quiet. On the other hand, when the clutch is disengaged, since the axial displacement of the flywheel is no more than 5% of the normal clutch stroke by means of the axial rigidity of the elastic plate being no less than 600 kg/mm, the failure of the disengagement of the clutch is effectively prevented.

FIG. 3 shows a crankshaft assembly for an internal combustion engine according to a second embodiment of the present invention. In FIG. 3, the same or like parts or members are denoted by the same reference numerals. In the following description, explanations of those same or like members will be omitted to avoid redundant description.

Further, though the clutch assembly is not shown in FIG. 3, the same clutch assembly including the clutch disc 9 and the clutch facing 8 is provided in the same manner as in FIG. 1.

In FIG. 3, the crankshaft 1 includes a stepped end surface having a first section la extending radially inward from its outer peripheral edge, a second section 1b extending axially from the inward end of the first section 1a toward the clutch disc 9, and a third circular section 1c extending radially from the second section 1b. The elastic plate 2 is of an annular shape having a mounting opening at its center for receiving the second section 1b therethrough. The elastic plate 2 is fixed to the crankshaft 1 with its axially extending inward end 2c facing the second section of the crankshaft 1 and with its radially extending inward end portion 2d facing the first section of the crankshaft. The other structure is substantially the same as in FIG. 1.

As mentioned in the background art, when the flywheel body 5 is rotated through the crankshaft 1, an axial run-out is generated on the radial surface 5g due to the processing error and the assembling error of the elastic plate 2 and the flywheel body 5 to cause the vibration when the clutch is engaged. The vibration further causes the fore and aft vibration of the vehicle floor.

In order to overcome the above-noted problem, in this embodiment, the radial surface 5g is processed in a manner to make an amount of the axial run-out no more than 0.1 mm. Specifically, the processing of the radial surface 5g is performed in the following manner.

The flywheel body 5 is first fixed to the elastic plate 2 by the bolts 6. Then, this unit is assembled to the crankshaft 1 with the axially extending inward end 2c of the elastic plate 2 facing the second section 1b of the crankshaft 1 and with

flywheel

<u>engaging</u>

engaging

engaging

Birthair ann im oil

U.S. Patent No. 5,465,635 Reissue Application Art Unit: 3502

-7(i)

the radially extending inward end portion 2d facing the first section 1a of the crankshaft. Thus, the crankshaft 1, elastic plate 2, flywheel body 5 and reinforcing member 4 are assembled into a unit 15. Then, the radial engaging surface 5g is processed based on the assembled condition between the axially extending inward end 2c and the second section 1b and/or between the radially extending inward end portion 2d and the first section 1a to make the axial runout of the radial engaging surface 5g no more than 0.1 mm.

By using the above-noted manner, the radial <u>engaging</u> surface 5g is easily and precisely processed to make the amount of the axial run-out no more than 0.1 mm.

Fig. 4 is a graph of axial run-out amount of flywheel a tacker (radial engaging surface 5g) versus fore and aft vibration of vehicle floor showing a result of experiments. It is confirmed that the fore and aft vibration of the vehicle floor which does not give an uncomfortable feeling to a human body is normally no more than 0.1 G (gravitational acceleration). As can be seen from FIG. 4, a fore and aft vibration of the vehicle floor is substantially in direct proportion to an amount of the axial run-out of the radial engaging surface 5g, and the fore and aft vibration becomes no more than 0.1 G when the axial run-out becomes no more

10

5

15

20

U.S. Patent No. 5,465,635 Reissue Application Art Unit: 3502

-7(ii) -

than 0.1 mm. Accordingly, by making the amount of the axial run-out no more than 0.1 mm as in this embodiment, the fore and aft vibration can be made no more than 0.1 G.

5

10

15

20

As understood from the above description, in this second embodiment, when the crankshaft 1 is rotated, the flywheel body 5 is ensured to rotate with the crankshaft 1 by means of the large circumferential rigidity of the elastic plate 2. Since the amount of the axial run-out of the radial engaging surface 5g is no more than 0.1 mm, the engagement between the radial engaging surface 5g and the clutch facing 8 is performed quite smoothly, so that the fore and aft vibration does not exceed 0.1 G. Accordingly, the driving power is transmitted from the engine to the transmission without giving the uncomfortable feeling to the human body.

Fig. 5 shows the central part of the flywheel assembly shown in Fig. 3 in more detail.

As in the first embodiment, the annular reinforcing member 4 of the second embodiment extends axially from a first member end 4h to a second member end 4i, as shown in Fig. 5. The axial length of the reinforcing member 4 is the distance D1 between the first and second member ends 4h and 4i. The reinforcing member 4 has an inner portion 4f having an abutment surface which defines the first member end 4h of

U.S. Patent No. 5,465,635 Reissue Application Art Unit: 3502

5

10

15

20

-7(iii)

the reinforcing member 4. The abutment surface 4h of the reinforcing member 4 is in contact with the inner end portion 2d of the elastic plate 2. The inner end portion 2d of the elastic plate 2 has first and second side surfaces which extend radially in parallel to each other. The first side surface of the inner end portion 2d of the elastic plate 2 faces leftward as viewed in Fig. 5, and the second side surface faces rightward. The abutment surface of the reinforcing member 4 faces leftward as viewed in Fig. 5. The leftward facing abutment surface of the reinforcing member 4 is in contact with the rightward facing second side surface of the inner end portion 2d of the elastic plate 2. The leftward facing first side surface of the inner portion 2d of the elastic plate-2 is in contact with the end surface to great of the crankshaft 1. The first and second side surfaces of the inner portion 2d of the elastic plate 2 extend in a radial direction which is perpendicular to the axial direction of the crankshaft 1. The first and second side surfaces of the inner end portion 2d of the elastic plate 2 are clamped between the abutment surface of the reinforcing member 4 and the end surface of the crankshaft 1, as shown in Fig. 5.

The reinforcing member 4 has the received portion 4a received in the central hole 5b of the flywheel body 5. The

5

10

15

20

-7(iv) -

received portion 4a of the reinforcing member 4 is cylindrical, and in sliding contact with the first surface section 5c of the flywheel body 5 as in the first embodiment. That is, the cylindrical received portion 4a of the reinforcing member 4 has an outside cylindrical surface facing radially outwardly, the first surface section 5c of the flywheel body 5 is an inwardly facing inside cylindrical surface defining the circular center hole 5b, and the cylindrical received portion 4a of the reinforcing member 4 is fit in the center hole 5b of the flywheel body 5 with a radial clearance 12 to form a loose fit. The radial clearance 12 is shown somewhat exaggeratingly in Fig. 5. Each of the elastic plate 2, the reinforcing member 4 and the flywheel body 5 is a rotating member rotating about a center axis C-C shown in Fig. 3, and in the form of a solid of revolution (or solid of rotation) about the center line C-C as shown in Fig. 3. The reinforcing member 4 has an outer circumferential surface which is a surface of revolution generated by rotating a curved line (4j, 4k) about the center line C-C. The outer circumferential surface extends from the abutment surface 4h of the reinforcing member 4 toward the second member end 4i. In this embodiment, the outer circumferential surface of the reinforcing member 4 has an outer cylindrical surface

U.S. Patent No. 5,465,635 Art Unit: 3502

5

10

15

-7(v)

section 4j fit in the central hole 5b of the flywheel body 5, and an outer curved surface section 4k which extends continuously from the outer cylindrical surface section 4j to the abutment surface 4h as shown in Figs. 3 and 5. Between the outward flange 4b and the abutment surface 4h, the outer circumferential surface (4j, 4k) is continuous such that the outer circumferential surface has no abrupt projection and no abrupt depression. The curved surface section 4k is a surface of revolution whose diameter <u>decreases</u> continuously from the diameter of the cylindrical surface section 4i toward the abutment surface 4h, as shown in Figs. 3 and 5. The curved surface section 4k extends from the abutment surface 4h to a curved surface end 4h at which the diameter becomes equal to the diameter of the cylindrical surface section 4j. The curved surface end 4n is located axially between the side surface 5f of the flywheel body 5 and the engaging surface 5g of the flywheel body 5.

The engaging surface 5g of the flywheel body 5 is a

rotating surface lying in an imaginary flat plane P-P shown
in Fig. 3. The second member end 4i of the reinforcing
member 4 is located axially between the engaging surface 5g
and the first side surface 5f of the flywheel body 5. The
second member end 4i is spaced away from the imaginary flat

U.S. Patent No. 5,465,635 Art Unit: 3502

5

10

15

20

-7(vi)

plane P-P toward the elastic plate 2. The axial distance D1 of the second member end 4i from the abutment surface 4h of the reinforcing member 4 is smaller than the axial distance D2 of the engaging surface 5g of the flywheel body 5 from the abutment surface 4h of the reinforcing member 4, as shown in Fig. 5.

As shown in Fig. 5, the outward flange 4b of the reinforcing member 4 has an abutting surface 4m confronting the second surface section 5d of the flywheel body 5, and the axial clearance 10 in the example shown in Fig. 5 is defined between the abutting surface 4m and the second surface section 5d of the flywheel body 5. The axial clearance 11 is defined between the side surface 5f of the flywheel body 5 and a side surface 2g of the elastic plate 2, as shown in Fig. 5.

As shown in Fig. 5, the reinforcing member 4 has a bolt hole 4p, and the elastic plate 2 has a bolt hole 2p. The elastic plate 2 is clamped axially between the reinforcing member 4 and the shaft end of the crankshaft 1 by the bolt 3 passing through the bolt holes 4p and 2p of the reinforcing member 4 and the elastic plate 2. The bolt hole 2p of the elastic plate 2 is located axially between the bolt hole 4p of the reinforcing member 4 and the shaft end of the crankshaft 1.
